Plan for today

- Michael and Scott unbounded queue 1996
- Progress concepts
 - Wait-free, lock-free, obstruction-free
- Union-find data structure
- Work-stealing dequeues
 - Chase-Lev dequeue 2005

Based on slides by Peter Sestoft

More on volatile and CAS speed

- Int field increment:
- data.x = data.x + 1;
- Single thread; and non-volatile or volatile
- AtomicInteger "incr":
 - Single thread

```
int old = data.get();
data.compareAndSet(old, old+1);
```

- Single thread, one other interfering thread
- Single thread, one other non-interfering thread

Results

Activity	Time/ns
Non-volatile field x	0.9
Volatile field x	8.8
CAS alone	11.4
CAS with interfering thread	74.5
CAS with non-interfering thread	11.7

Lock-based queue with sentinel

```
class LockingQueue<T> implements UnboundedQueue<T> {
                                                                        TestMSqueue.java
  private Node<T> head, tail;
                                                          Make
  public LockingQueue() {
                                                    sentinel node
    head = tail = new Node<T>(null, null);
                                           Invariants:
                                           head≠null
private static class Node<T> {
                                           tail.next=null
  final T item;
                                           If empty, head=tail
  Node<T> next;
                                           If non-empty: head≠tail,
                                                  head.next is first item,
                                                   tail points to last item
  tail
  head
                                               9
              sentinel
```

Lock-based queue operations

```
public synchronized void enqueue(T item) {
 Node<T> node = new Node<T>(item, null);
  tail.next = node;
                                                 Enqueue
  tail = node;
                                                  at tail
                               Atomic
public synchronized T dequeue() {
                                              Dequeue
  if (head.next == null)
                                            from second
   return null;
 Node<T> first = head;
                                            node, second
 head = first.next;
                                            becomes new
  return head.item;
                                               sentinel
                            Atomic
```

- Important property:
 - Enqueue (put) updates tail but not head
 - Dequeue (take) updates head but not tail

Michael-Scott lock-free queue, CAS

```
private static class Node<T> {
  final T item;
  final AtomicReference<Node<T>> next;
}
```

Michael and Scott: Simple, Fast, and Practical Non-Blocking and Blocking Concurrent Queue Algorithms, 1996

```
class MSQueue<T> implements UnboundedQueue<T> {
  private final AtomicReference<Node<T>> head, tail;

public MSQueue() {
   Node<T> dummy = new Node<T>(null, null);
   head = new AtomicReference<Node<T>> (dummy);
   tail = new AtomicReference<Node<T>> (dummy);
}
```

- If non-empty:
 - As before, head.next is first item
 - But tail points to last item ("quiescent state")
 or second-last item ("intermediate state")

Michael & Scott queue operations

Michael-Scott dequeue (take)

```
public T dequeue() {
  while (true) {
    Node<T> first = head.get(),
             last = tail.get(),
Needed?
             next = first.next.get();
     if (first == head.get()) {
       if (first == last) {
                                 May be empty
         if (next == null)
           return null;
                                 Is empty
                                                 Intermediate,
         else
                                                  try move tail
           tail.compareAndSet(last, next);
       } else {
         T result = next.item;
         if (head.compareAndSet(first, next))
                                                     Try move
           return result;
                                                        head
```

Michael-Scott enqueue (put)

```
public void enqueue(T item) { // at tail
  Node<T> node = new Node<T>(item, null);
  while (true) {
    Node<T> last = tail.get(),
            next = last.next.get();
    if (last == tail.get()) {
                                  Quiescent, try add
      if (next == null)
        if (last.next.compareAndSet(next, node)) {
          tail.compareAndSet(last, node);
                                                 Success, try
          return;
                                                   move tail
      } else {
        tail.compareAndSet(last, next);
                                                 Intermediate,
                                                 try move tail
                                                 "help another
                                                  enqueuer"
```

After Herlihy & Shavit p. 233

TestMSqueue.java

Why must dequeue mess with the tail?

```
Scenario without it: If queue empty, head==tail
```

A: enqueue(7)

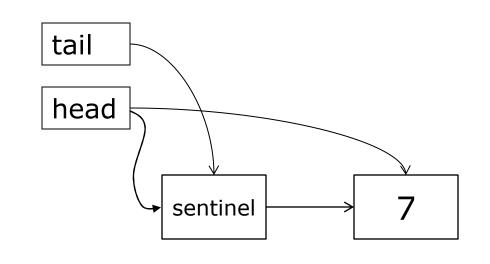

A: update a.next

B: dequeue()

B: update head

Now tail lags behind head, not good So B: dequeue() must move tail before moving head

```
public T dequeue() {
    ...
    if (first == last) {
        if (next == null)
            return null;
        else
            tail.compareAndSet(last, next);
    } else ....
}
Intermediate,
    try move tail
```

Understanding Michael-Scott queue

- Linearization point: where method takes effect
- Linearizable, with linearization points:
 - enqueue: successful CAS at E9
 - dequeue returning null: D3
 - dequeue returning item: successful CAS at D13

```
public T dequeue() { // from head
  while (true) {
                                    D3
    Node<T> first = head.get(),
            last = tail.get(),
            next = first.next.get();
    if (first == head.get()) { // D5
      if (first == last) {
        if (next == null)
          return null;
        else
          tail.compareAndSet(last, next);
      } else {
        T result = next.item;
        if (head.compareAndSet(first, next))
          return result;
                                    D13
```

Nice, but ... needs a lot of AtomicReference objects

```
private static class Node<T> {
   final T item;
   volatile Node<T> next;
   ...
}
```

Better, no
AtomicReference
object needed

Instead, make an "updater"

Michael-Scott enqueue, using the "updater" for last.next

```
public void enqueue(T item) { // at tail
  Node<T> node = new Node<T>(item, null);
  while (true) {
    Node<T> last = tail.get(), next = last.next;
    if (last == tail.get()) {
      if (next == null) {
        if (nextUpdater.compareAndSet(last, next, node)) {
          tail.compareAndSet(last, node);
                                            If "next" field of
          return;
                                              last equals
      } else {
                                           next, set to node
        tail.compareAndSet(last, next);
```

Plan for today

- Michael and Scott unbounded queue 1996
- Progress concepts
 - Wait-free, lock-free, obstruction-free
- Work-stealing dequeues
 - Chase-Lev dequeue 2005
- Union-find data structure

Progress concepts

- Non-blocking: A call by thread A cannot prevent a call by thread B from completing
 - Not true for lock-based queue: A holds lock to put(), gets descheduled or crashes, while B wants to take() but cannot get lock
- Wait-free: Every call finishes in finite time
 - True for SimpleTryLock's tryLock
 - Not true for AtomicInteger's getAndAdd
- Bounded wait-free: Every ... in bounded time
- Lock-free: Some call finishes in finite time
 - True for AtomicInteger's getAndAdd
 - Any wait-free method is also lock-free
 - Lock-free is wait-free in expected case

Obstruction freedom

- Obstruction-free: If a method call executes alone, it finishes in finite time
 - Lock-based data structures are not obstruction-free
 - A lock-free method is also obstruction-free
 - Obstruction-free sounds rather weak, but in combination with back-off it ensures progress
 - Some people even think it too strong:

... we argue that obstruction-freedom is not an important property for software transactional memory, and demonstrate that, if we are prepared to drop the goal of obstruction-freedom, software transactional memory can be made significantly faster

Ennals 2006: STM should not be obstruction-free

Plan for today

The union-find data structure

- Efficient way to maintain equivalence classes
- Used in

Tarjan: Data structures and network algorithms, 1983

- type inference in compilers: F#, Scala, C# ...
- image segmentation
- network analysis: chips, WWW, Facebook friends ...
- Example: family relations, who are related?

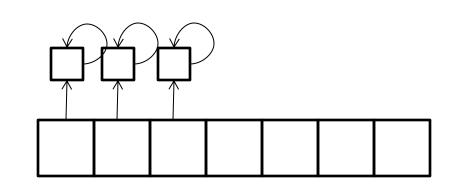

Sue is Pat's sister Alice is Bob's sister Mary is John's mother Mary is Bob's mother

Are Sue and Mary related?

Three union-find implementations

- A: Coarse-locking = Synchronized methods
- B: Fine-locking = Lock on each set partition
- C: Wait-free = Optimistic, CAS-based

```
interface UnionFind {
  int find(int x);
  void union(int x, int y);
  boolean sameSet(int x, int y);
}
```

```
class Node {
   volatile int
   next, rank;
}
```

```
class CoarseUnionFind implements UnionFind {
  private final Node[] nodes;

public CoarseUnionFind(int count) {
    this.nodes = new Node[count];
    for (int x=0; x<count; x++)
        nodes[x] = new Node(x);
}</pre>
```

Coarse-locking union-find

```
class CoarseUnionFind implements UnionFind {
                                                                            TestUnionFind.java
  private final Node[] nodes;
                                                           Path
  public synchronized int find(int x) {
                                                          halving
    while (nodes[x].next != x) {
      final int t = nodes[x].next, u = nodes[t].next;
      nodes[x].next = u;
      x = u;
    return x;
  public synchronized void union(int x, int y) {
    int rx = find(x), ry = find(y);
                                                   Find
    if (rx == ry)
                                                  roots
      return;
    if (nodes[rx].rank > nodes[ry].rank) {
      int tmp = rx; rx = ry; ry = tmp;
                                                             rx
    nodes[rx].next = ry;
    if (nodes[rx].rank == nodes[ry].rank)
      nodes[ry].rank++;
                                              Union
                                             by rank
```

Fine-locking union-find

- No locking in find
 - Do path compression separately
 - Ensure visibility by volatile next, rank in Node

```
class FineUnionFind implements UnionFind {
  public int find(int x) {
    while (nodes[x].next != x)
                                        No path
      x = nodes[x].next;
                                        halving
    return x;
  // Assumes lock is held on nodes[root]
  private void compress(int x, final int root) {
    while (nodes[x].next != x) {
                                            Path
      int next = nodes[x].next;
                                        compression
      nodes[x].next = root;
      x = next;
```

Fine-locking union-find

```
public void union(final int x, final int y) {
  while (true) {
    int rx = find(x), ry = find(y);
    if (rx == ry)
      return;
    else if (rx > ry) {
                                                  Consistent
      int tmp = rx; rx = ry; ry = tmp;
                                                  lock order
    synchronized (nodes[rx]) {
      synchronized (nodes[ry]) {
                                                                 Restart if
        if (nodes[rx].next != rx || nodes[ry].next != ry)
                                                                 updated
          continue;
        if (nodes[rx].rank > nodes[ry].rank) {
          int tmp = rx; rx = ry; ry = tmp;
                                                           Union by rank
        nodes[rx].next = ry;
                                                              and path
        if (nodes[rx].rank == nodes[ry].rank)
                                                            compression
          nodes[ry].rank++;
        compress(x, ry);
        compress(y, ry);
```

Wait-free union-find with CAS

```
class Node {
   private final AtomicInteger next;
   private final int rank;
}
```

```
Anderson and Woll: Wait-free parallel algorithms for the union-find problem, 1991
```

Path halving with CAS

Atomic update of root nodes[x] to point to fresh Node(y,newRank)

```
boolean updateRoot(int x, int oldRank, int y, int newRank) {
  final Node oldNode = nodes.get(x);
  if (oldNode.next.get() != x || oldNode.rank != oldRank)
    return false;
  Node newNode = new Node(y, newRank);
  return nodes.compareAndSet(x, oldNode, newNode);
}
```

Wait-free union-find: union

```
public void union(int x, int y) {
  int xr, yr;
  do {
    x = find(x);
    y = find(y);
    if (x == y)
      return;
    xr = nodes.get(x).rank;
    yr = nodes.get(y).rank;
    if (xr > yr \mid | xr == yr && x > y) {
      { int tmp = x; x = y; y = tmp; }
      { int tmp = xr; xr = yr; yr = tmp; }
  } while (!updateRoot(x, xr, y, xr));
  if (xr == yr)
    updateRoot(y, yr, y, yr+1);
  setRoot(x);
```

Java 8 source

.NET

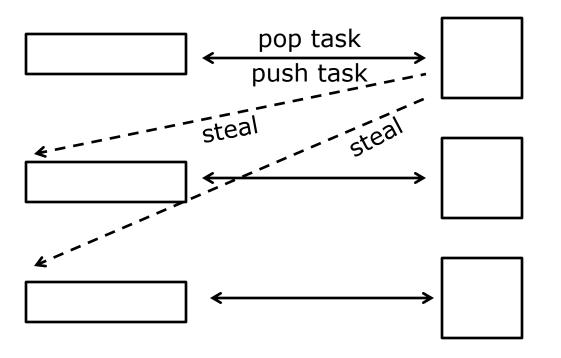

A worker/task framework

- Worker threads pop and push tasks on queue
- Not scalable because single queue is used

Better worker/task framework

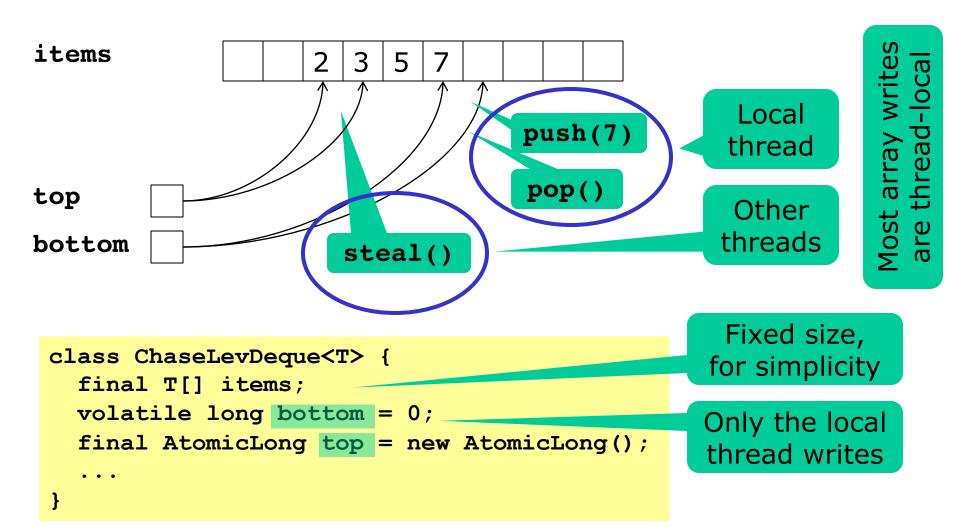

Thread-local workstealing dequeues Worker threads

```
interface WSDeque<T> {
  void push(T item);
  T pop();
  T steal();
}
```

- Fewer memory write conflicts:
 - Most queue accesses are from local thread only
 - Pop from bottom, steal from top, conflicts are rare
- Much better scalability

Chase-Lev workstealing queue (2005)

- push and pop at bottom: stack for local thread
- steal at top: queue for other threads

Chase-Lev push at bottom

```
public void push(T item) {
  final long b = bottom, t = top.get(), size = b - t;
  if (size == items.length)
    throw new RuntimeException("queue overflow");
  items[index(b, items.length)] = item;
  bottom = b+1;
}
```

- This is thread-safe, even without locks or CAS
 - Only one thread calls push
 - So only one thread *updates* the **bottom** field
 - Other threads read it, so it must be volatile

Chase-Lev steal at top

```
public T steal() {
  final long t = top.get(), b = bottom, size = b - t;
  if (size <= 0)
    return null;
  else {
    T result = items[index(t, items.length)];
    if (top.compareAndSet(t, t+1))
        return result;
    else
        return null;
    }
}</pre>
Somebody else
stole top item
```

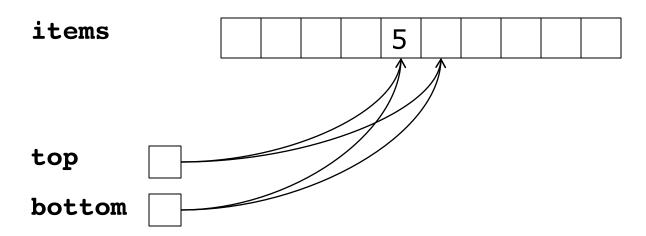

- Several threads may call steal
 - And try to increment top, hence an AtomicLong
 - So steal may fail (with null) due to interference
 - even if queue is non-empty
 - OK because callers keep stealing until success

Chase-Lev pop at bottom

```
public T pop() {
  final long b = bottom - 1;
  bottom = b:
  final long t = top.get(), afterSize = b - t;
  if (afterSize < 0) {</pre>

                                              ... so write top
      bottom = t+1;
                                              then set bottom
      return result;
                                             Oops, somebody
                                               stole last item
```

Why does pop update top?

- If pop takes the last item, it may clash with a concurrent steal operation
 - Because then **size** == **0** and so **bottom** == **top**

- Hence pop must
 - check top is unchanged (nobody stole item yet)
 - if so, update top so stealers know item is taken
 - both done by top.compareAndSet(t, t+1)

Linearization points

- When does steal take effect?
- When does push take effect?
- When does pop take effect?
